Stability analysis

ABSTRACT

New interval observers are designed for linear systems with time-varying delays in the case of delayed measurements. Interval observers employ positivity and stability analysis of the estimation error system, which in the case of delayed measurements should be delay-dependent. New delay-dependent conditions of positivity for linear systems with time-varying delays are introduced. Efficiency of the obtained solution is demonstrated by examples.

1. Introduction

An estimation in nonlinear delayed systems is rather complicated (Fridman, 2014; Sipahi, Niculescu, Abdallah, Michiels, & Gu, 2011), as well as analysis of functional differential equations (Richard, 2003). Especially the observer synthesis is problematic for the cases when the model of a nonlinear delayed system contains parametric and/or signal uncertainties, or when the delay is time-varying and/or uncertain (Briat, Sename, & Lafay, 2011; Califano, Marquez-Martinez, & Moog, 2011; Zheng, Barbot, Boutat, Floquet, & Richard, 2011), the frequent applications include biosystems and chemical processes. Delayed measurements usually also increase complexity of estimators, which is a case in networked systems. An observer solution for these more complex situations is

highly demanded in these and many others applications. Interval or set-membership estimation is a promising framework to observation in uncertain systems (Gouzé, Rapaport, & Hadj-Sadok, 2000; Jaulin, 2002; Kieffer & Walter, 2004; Mazenc & Bernard, 2011; Moisan, Bernard, & Gouzé, 2009; Raïssi, Efimov, & Zolghadri, 2012), when all uncertainty is included in the corresponding intervals or polytopes, and as a result the set of admissible values (an interval) for the state is provided at each instant of time.

In this work an interval observer for time-delay systems with delayed measurements is proposed. A peculiarity of an interval observer is that in addition to stability conditions, some restrictions on positivity of estimation error dynamics have to be imposed (in order to envelop the system solutions). The existing solutions in the field (Efimov, Perruquetti, & Richard, 2013; Efimov, Polyakov, & Richard, 2015; Mazenc, Niculescu, & Bernard, 2012; Polyakov, Efimov, Perruquetti, & Richard, 2013) are based on the delay-independent conditions of positivity from Ait Rami (2009) and Haddad and Chellaboina (2004). Some results on interval observer design for uncertain time-varying delay can be found in Efimov et al. (2013) and Ait Rami, Schönlein, and Jordan (2013). The first objective of this work is to use the delay-dependent positivity conditions (Efimov, Polyakov, Fridman, Perruquetti, & Richard, 2015), which are based on the theory of non-oscillatory solutions for functional differential equations (Agarwal, Berezansky, Braverman, & Domoshnitsky, 2012; Domoshnitsky, 2008). interval observers are designed for linear systems with delayed measurements (with time-varying delays) in the case of observable and detectable systems (with respect to (Efimov et al., 2015) the present work contains new result, Theorem 12, relaxed Assumption 1, and new examples). Efficiency of the obtained interval observers is demonstrated on a benchmark example from Mazenc et al. (2012) and a delayed nonlinear pendulum.

The paper is organized as follows. Some preliminaries and notation are given in Section 2. The delay-dependent positivity conditions are presented in Section 3. The interval observer design is performed for a class of linear time-delay systems (or a class of nonlinear systems in the output canonical form) with delayed measurements in Section 4. Examples of numerical simulation are presented in Section 5.

2. Preliminaries

2.1. Notation

- \mathbb{R} is the Euclidean space ($\mathbb{R}_+ = \{\tau \in \mathbb{R} : \tau \geq 0\}$), $\mathcal{C}_\tau^n = C([- \tau, 0], \mathbb{R}^n)$ is the set of continuous maps from $[- \tau, 0]$ into \mathbb{R}^n for $n \geq 1$; $\mathcal{C}_{\tau+}^n = \{y \in \mathcal{C}_\tau^n : y(s) \in \mathbb{R}_+^n, s \in [- \tau, 0]\}$;
- x_t is an element of \mathcal{C}_τ^n defined as $x_t(s) = x(t + s)$ for all $s \in [- \tau, 0]$;
- $|x|$ denotes the absolute value of $x \in \mathbb{R}$, $\|x\|_2$ is the Euclidean norm of a vector $x \in \mathbb{R}^n$, $\|\varphi\| = \sup_{t \in [- \tau, 0]} \|\varphi(t)\|_2$ for $\varphi \in \mathcal{C}_\tau^n$;
- for a measurable and locally essentially bounded input $u : \mathbb{R}_+ \rightarrow \mathbb{R}^p$ the symbol $\|u\|_{[t_0, t_1]}$ denotes its L_∞ norm $\|u\|_{[t_0, t_1]} = \text{ess sup}\{\|u(t)\|_2, t \in [t_0, t_1]\}$, the set of all such inputs $u \in \mathbb{R}^p$ with the property $\|u\|_{[0, +\infty)} < \infty$ will be denoted as \mathcal{L}_∞^p ;
- for a matrix $A \in \mathbb{R}^{n \times n}$ the vector of its eigenvalues is denoted as $\lambda(A)$;
- I_n and $0_{n \times m}$ denote the identity and zero matrices of dimensions $n \times n$ and $n \times m$, respectively;
- $a \mathcal{R} b$ corresponds to an elementwise relation $\mathcal{R} \in \{<, >, \leq, \geq\}$ (a and b are vectors or matrices): for example $a < b$ (vectors) means $\forall i : a_i < b_i$; for $\phi, \varphi \in \mathcal{C}_\tau$ the relation $\phi \mathcal{R} \varphi$ has to be understood elementwise for whole domain of definition of the functions, i.e. $\phi(s) \mathcal{R} \varphi(s)$ for all $s \in [- \tau, 0]$;
- for a symmetric matrix Υ , the relation $\Upsilon < 0$ ($\Upsilon \leq 0$) means that the matrix is negative (semi) definite.

2.2. Delay-independent conditions of positivity

Consider a time-invariant linear system with time-varying delay:

$$\begin{aligned} \dot{x}(t) &= A_0 x(t) - A_1 x(t - \tau(t)) + b(t), \quad t \geq 0, \\ x(\theta) &= \phi(\theta) \quad \text{for } -\bar{\tau} \leq \theta \leq 0, \quad \phi \in \mathcal{C}_{\bar{\tau}}^n, \end{aligned} \quad (1)$$

where $x(t) \in \mathbb{R}^n$, $x_t \in \mathcal{C}_\tau^n$ is the state function; $\tau : \mathbb{R}_+ \rightarrow [-\bar{\tau}, 0]$ is the time-varying delay, a Lebesgue measurable function of time, $\bar{\tau} \in \mathbb{R}_+$ is the maximum delay; $b \in \mathcal{L}_\infty^n$ is the input; the constant matrices A_0 and A_1 have appropriate dimensions. The matrix A_0 is called Metzler if all its off-diagonal elements are nonnegative. The system (1) is called *positive* if for $x_0 \geq 0$ it has the corresponding solution $x(t) \geq 0$ for all $t \geq 0$.

Lemma 1 (Ait Rami, 2009 and Haddad & Chellaboina, 2004). *The system (1) is positive iff A_0 is Metzler, $A_1 \leq 0$ and $b(t) \geq 0$ for all $t \geq 0$. A positive system (1) is asymptotically stable for $b(t) \equiv 0$ for all $\bar{\tau} \in \mathbb{R}_+$ iff there are $p, q \in \mathbb{R}_+^n$ ($p > 0$ and $q > 0$) such that*

$$p^T [A_0 - A_1] + q^T = 0.$$

Under conditions of the above lemma the system has bounded solutions for $b \in \mathcal{L}_\infty^n$. Note that for linear time-invariant systems

the conditions of positive invariance of polyhedral sets have been similarly given in Dambrine, Richard, and Borne (1995), as well as conditions of asymptotic stability in the nonlinear case have been considered in Borne, Dambrine, Perruquetti, and Richard (2003) and Dambrine and Richard (1993, 1994).

3. Delay-dependent conditions of positivity

Consider a scalar time-varying linear system with time-varying delays (Agarwal et al., 2012):

$$\begin{aligned} \dot{x}(t) &= a_0(t)x[g(t)] - a_1(t)x[h(t)] + b(t), \\ x(\theta) &= 0 \quad \text{for } \theta < 0, \quad x(0) \in \mathbb{R}, \end{aligned} \quad (2)$$

where $a_0 \in \mathcal{L}_\infty, a_1 \in \mathcal{L}_\infty, b \in \mathcal{L}_\infty, h(t) - t \in \mathcal{L}_\infty, g(t) - t \in \mathcal{L}_\infty$ and $h(t) \leq t, g(t) \leq t$ for all $t \geq 0$. For the system (2) the initial condition in (3) is, in general, not a continuous function (if $x(0) \neq 0$).

The following result proposes delay-independent positivity conditions.

Lemma 2 (Agarwal et al., 2012, Corollary 15.7). *Let $h(t) \leq g(t)$ and $0 \leq a_1(t) \leq a_0(t)$ for all $t \geq 0$. If $x(0) \geq 0$ and $b(t) \geq 0$ for all $t \geq 0$, then the corresponding solution of (2), (3) $x(t) \geq 0$ for all $t \geq 0$.*

Recall that in this case positivity is guaranteed for “discontinuous” initial conditions. The peculiarity of the condition $0 \leq a_1(t) \leq a_0(t)$ is that it may correspond to an unstable system (2). In order to overcome this issue, delay-dependent conditions can be introduced.

Lemma 3 (Agarwal et al., 2012, Corollary 15.9). *Let $h(t) \leq g(t)$ and $0 \leq \frac{1}{e} a_0(t) \leq a_1(t)$ for all $t \geq 0$ with*

$$\sup_{t \in \mathbb{R}_+} \int_{h(t)}^t \left[a_1(\xi) - \frac{1}{e} a_0(\xi) \right] d\xi < \frac{1}{e},$$

where $e = \exp(1)$. *If $x(0) \geq 0$ and $b(t) \geq 0$ for all $t \geq 0$, then $x(t) \geq 0$ for all $t \geq 0$ in (2), (3).*

These lemmas describe positivity conditions for the system (2), (3), which is more complex than (1), but scalar, they can also be extended to the n -dimensional system (1).

Corollary 4. *The system (1) with $b(t) \geq 0$ for all $t \geq 0$ and initial conditions*

$$x(\theta) = 0 \quad \text{for } -\bar{\tau} \leq \theta < 0, \quad x(0) \in \mathbb{R}_+^n,$$

is positive if $-A_1$ is Metzler, $A_0 \geq 0$, and

$$0 \leq (A_0)_{i,i} \leq e(A_1)_{i,i} < (A_0)_{i,i} + \bar{\tau}^{-1}$$

for all $i = 1, \dots, n$.

From these corollaries it is easy to conclude that the delay-dependent case studied in Lemmas 2 and 3 is crucially different from the delay-independent positivity conditions given first in Lemma 1, where in the scalar case the restriction $a_1 \leq 0$ implies positivity of (1) and the condition $a_0 < a_1$ according to Lemma 1 ensures stability for any $\bar{\tau}$. These results do not contradict to Remark 3.1 of Haddad and Chellaboina (2004), since $x(\theta) \neq 0$ for $-\tau \leq \theta < 0$ there. A graphical illustration of different delay-independent conditions (positivity from Lemmas 1 and 2) and delay-dependent ones (from Lemma 3, the stability conditions are also satisfied in this case) for the system (2) is given in Fig. 1 in the plane (a_0, a_1) . It is worth stressing that an extension of the positivity domain in Lemma 3 is also achieved due to restrictions imposed on initial conditions in (3).

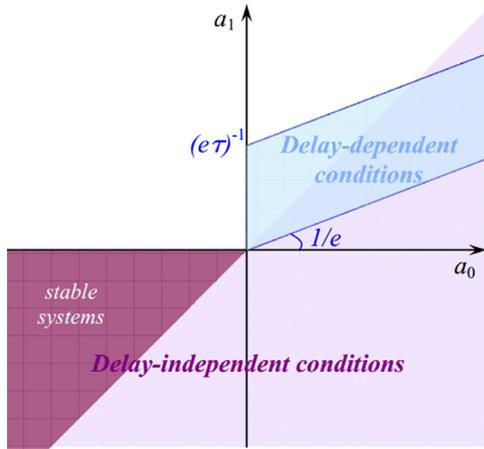

Fig. 1. Different positivity conditions for (2).

In order to use the results of Lemmas 2 and 3 it is necessary to pass from discontinuous initial conditions in (3) to continuous ones usually studied (Sipahi et al., 2011). Further, in this section we will be interested in the case

$$a_0(t) = a_0, \quad a_1(t) = a_1, \quad t - \bar{\tau} \leq h(t) \leq t, \quad g(t) = t, \quad (4)$$

where $\bar{\tau} > 0$ is maximum delay. Now let us extend the initial condition (3) with a continuous one (note that all developments above can be easily adopted for piecewise continuous initial conditions, such a reformulation is omitted for simplicity):

$$x(\theta) = \phi(\theta) \quad \text{for } \theta \in [-\bar{\tau}, 0], \quad \phi \in \mathcal{C}_{\bar{\tau}} \quad (5)$$

and consider the conditions providing delay-dependent positivity for (2), (4), (5).

Remark 5. As mentioned in Liu and Fridman (2014), the first delay interval $0 \leq t \leq \bar{\tau}$ is important for delay-dependent conditions giving solution bounds (and not just stability conditions).

Proposition 6. Let $0 \leq a_0 \leq ea_1 < a_0 + \bar{\tau}^{-1}$. If $x(0) \geq 0, b(t) \geq 0$ for all $t \geq 0$ and

$$b(t) \geq a_1\phi[h(t)] \quad \forall t \in \{0 \leq t \leq \bar{\tau} : h(t) < 0\},$$

then the corresponding solution of (2), (4), (5) satisfies $x(t) \geq 0$ for all $t \geq 0$.

Proof. Consider the following system

$$\begin{aligned} \dot{z}(t) &= a_0z(t) - a_1z[h(t)] + b(t) + \varphi(t), \\ z(\theta) &= 0 \quad \text{for } \theta \in [-\bar{\tau}, 0], \quad z(0) = \phi(0), \\ \varphi(t) &= \begin{cases} -a_1\phi[h(t)] & \text{if } h(t) < 0, \\ 0 & \text{otherwise,} \end{cases} \end{aligned}$$

which is of the form (2), (4), (3) with $z(0) = \phi(0)$ and $b(t) + \varphi(t) \geq 0$ for all $t \geq 0$ by the conditions. Since all conditions of Lemma 3 are satisfied, then $z(t) \geq 0$ for all $t \geq 0$. From another side, it is easy to check that the solution of (2), (4), (5) $x(t) = z(t)$ for all $t \geq 0$.

The following extension for n -dimensional system (1) can be obtained.

Corollary 7. The system (1) with $b(t) \geq 0$ for all $t \geq 0, x(0) \in \mathbb{R}_+^n$, with a Metzler matrix $-A_1, A_0 \geq 0$ and $0 \leq (A_0)_{i,i} \leq e(A_1)_{i,i} < (A_0)_{i,i} + \bar{\tau}^{-1}$ for all $i = 1, \dots, n$, has the corresponding solution $x(t) \geq 0$ for all $t \geq 0$ provided that

$$b(t) \geq A_1\phi(t - \tau(t)) \quad \forall t \in [0, \bar{\tau}].$$

Let us show how these conditions can be used for the design of interval observers.

4. Interval observer design under delayed measurements

In this section a useful inequality for interval analysis and a statement of the problem are given. Next, a motivating benchmark example from Mazenc et al. (2012) is investigated, using the results of the previous section, in order to clarify the main idea. Finally, a delay-dependent approach for an interval observer design is presented.

4.1. Interval bounds

Given a matrix $A \in \mathbb{R}^{m \times n}$ define $A^+ = \max\{0, A\}, A^- = A^+ - A$ and $|A| = A^+ + A^-$. Let $x \in \mathbb{R}^n$ be a vector variable, $\underline{x} \leq x \leq \bar{x}$ for some $\underline{x}, \bar{x} \in \mathbb{R}^n$, and $A \in \mathbb{R}^{m \times n}$ be a constant matrix, then (Efimov, Fridman, Raïssi, Zolghadri, & Seydou, 2012)

$$A^+\underline{x} - A^-\bar{x} \leq Ax \leq A^+\bar{x} - A^-\underline{x}. \quad (6)$$

4.2. Problem statement

Consider a linear system with a time-varying delay:

$$\begin{aligned} \dot{x}(t) &= A_0x(t) + A_1x[h(t)] + b(t), \\ y(t) &= Cx[h(t)] + v(t), \end{aligned} \quad (7)$$

where $x(t) \in \mathbb{R}^n, t - \bar{\tau} \leq h(t) \leq t$ is a known time-varying delay ($t - h(t) \in \mathcal{L}_\infty, \bar{\tau} > 0$ is maximum delay, $x_0 \in \mathcal{C}_{\bar{\tau}}^n; y(t) \in \mathbb{R}^p$ is the system output available for measurements with the noise $v \in \mathcal{L}_\infty^p; b \in \mathcal{L}_\infty^n$ is the system input; the constant matrices A_0, A_1 and C have appropriate dimensions. It is assumed that for given b and h the system has a unique solution defined at least locally. In the state and the output equations of (7) the same delay is used, that corresponds to a delay-free system with delayed measurements, for example, or a system closed by an output-based feedback. The input $b(t)$ can be a function of control, and it can also contain a delay.

Remark 8. Note that the results to be obtained for (7) can be easily extended to the case with multiple delays:

$$\begin{aligned} \dot{x}(t) &= A_0x(t) + \sum_{i=1}^q A_i x[h_i(t)] + b(t), \\ y(t) &= Cx[h_1(t)] + v(t), \end{aligned}$$

provided that $h_i(t) = t - \tau_i(t)$ and $h_i(t) \leq h_1(t)$ for all $t \geq 0$ (in this case an output injection $y[t - \tau_i(t) + \tau_1(t)] = Cx[h_i(t)] + v[t - \tau_i(t) + \tau_1(t)]$ can be used in observer). A compact form (7) is used in the paper for brevity of presentation.

Assumption 1. There exist known functions $\underline{x}_0, \bar{x}_0 \in \mathcal{C}_{\bar{\tau}}^n$ such that $\underline{x}_0(\theta) \leq x_0(\theta) \leq \bar{x}_0(\theta)$ for all $\theta \in [-\bar{\tau}, 0]$.

The assumption about a known set $[x_0, \bar{x}_0]$ for the initial conditions x_0 is standard for the interval or set-membership estimation theory (Efimov et al., 2013; Gouzé et al., 2000; Jaulin, 2002; Kieffer & Walter, 2004; Moisan et al., 2009). We will assume that the values of matrices A_0, A_1 and C are known and the instant values of the signals $b(t)$ and $v(t)$ are unavailable.

Assumption 2. There exist known signals $\underline{b}, \bar{b} \in \mathcal{L}_\infty^n$ and $\underline{v}, \bar{v} \in \mathcal{L}_\infty^p$ such that $\underline{b}(t) \leq b(t) \leq \bar{b}(t)$ and $\underline{v}(t) \leq v(t) \leq \bar{v}(t)$ for all $t \geq 0$.

Therefore, the uncertain inputs $b(t), h(t)$ and $v(t)$ in (7) belong to known intervals $[\underline{b}(t), \bar{b}(t)], [t - \bar{\tau}, t]$ and $[\underline{v}(t), \bar{v}(t)]$ respectively for all $t \geq 0$.

It is required to design an interval observer,

$$\dot{\xi}(t) = F[\xi_t, \underline{b}(t), \bar{b}(t), \underline{v}(t), \bar{v}(t), y(t)], \quad \xi_t \in \mathcal{C}_{\bar{\tau}}^s,$$

$$\underline{x}(t) = \underline{G}[\xi_t, \underline{b}(t), \bar{b}(t), \underline{v}(t), \bar{v}(t), y(t)],$$

$$\bar{x}(t) = \bar{G}[\xi_t, \underline{b}(t), \bar{b}(t), \underline{v}(t), \bar{v}(t), y(t)],$$

such that $\underline{x}(t) \leq x(t) \leq \bar{x}(t)$ for all $t > 0$ provided that $\underline{x}_0 \leq x_0 \leq \bar{x}_0$, and $x - \underline{x}, \bar{x} - x \in \mathcal{L}_{\infty}^n, s > 0$. A similar problem has been studied in Mazenc et al. (2012) but for constant delays.

4.3. Motivating example

Consider a motivating example introduced in Mazenc et al. (2012), where the problem of a 1-framer¹ design has been posed for a scalar system

$$\dot{x}(t) = -x(t - \tau) \quad (8)$$

with initial condition $x_0 \in \mathcal{C}_{\tau}$. This system is globally asymptotically stable if $\tau < \frac{\pi}{2}$. It has been proven in Mazenc et al. (2012) (Proposition 3.2) that this system has no 1-framer of the form

$$F(\xi_t) = F_1 \xi(t) + F_2 \xi(t - \tau),$$

$$\underline{C}(\xi_t) = H_1 \xi(t), \quad \bar{C}(\xi_t) = H_2 \xi(t), \quad (9)$$

where $\xi_t \in \mathcal{C}_{\bar{\tau}}^s$ for any $s \geq 1$ and F_i, H_i ($i = 1, 2$) are matrices of appropriate dimensions.

Applying the result of Proposition 6, the system (8) has positive solutions for a discontinuous initial condition (3) with $x(0) \geq 0$ if $\tau < \frac{1}{e}$. Actually in this case it has a non-oscillating solution which is asymptotically converging to zero (since $\frac{1}{e} < \frac{\pi}{2}$), and which does not cross the zero level for all $t \in \mathbb{R}_+$. Further, using the result of Proposition 6, we can design a 1-framer for (8) having the form (9) for $t \geq \tau$.

Claim 9. For the system (8) with any initial condition $x_0 \in \mathcal{C}_{\tau}$ and $\tau < \frac{1}{e}$, the system

$$\dot{\underline{x}}(t) = -\underline{x}(t - \tau) - \delta(\|\bar{x}_0 - \underline{x}_0\|),$$

$$\dot{\bar{x}}(t) = -\bar{x}(t - \tau) + \delta(\|\bar{x}_0 - \underline{x}_0\|),$$

$$\delta(s) = \begin{cases} s & \text{if } t \leq \tau, \\ 0 & \text{otherwise} \end{cases}$$

is a 1-framer, i.e. $\underline{x}(t) \leq x(t) \leq \bar{x}(t)$ for all $t > 0$, provided that $\underline{x}_0 \leq x_0 \leq \bar{x}_0, \underline{x}_0, \bar{x}_0 \in \mathcal{C}_{\tau}$, and $\underline{x}, \bar{x} \in \mathcal{L}_{\infty}^n$.

Proof. Introducing the interval estimation errors $\underline{e} = x - \underline{x}$ and $\bar{e} = \bar{x} - x$ we obtain

$$\dot{\underline{e}} = -\underline{e}(t - \tau) + \delta(\|\bar{x}_0 - \underline{x}_0\|),$$

$$\dot{\bar{e}} = -\bar{e}(t - \tau) + \delta(\|\bar{x}_0 - \underline{x}_0\|)$$

with $\underline{e}_0 \geq 0$ and $\bar{e}_0 \geq 0$. All conditions of Proposition 6 are satisfied for the equations describing the error dynamics with $\tau < \frac{1}{e}$, then $\underline{e}(t) \geq 0$ and $\bar{e}(t) \geq 0$ for all $t \geq 0$.

Therefore, a 1-framer of a form similar to (9) can be designed for (8) with a restricted value of delay $\tau < \frac{1}{e}$ (it differs from (9) only on the interval $[0, \tau]$). The results of simulation for this example are given in Section 5.

Let us extend this idea of interval observer design to a more generic system (7).

4.4. Delay-dependent conditions for interval estimation

The Eq. (7) can be rewritten as follows:

$$\dot{x}(t) = A_0 x(t) + (A_1 - LC)x[h(t)] + Ly(t) + b(t) - Lv(t),$$

where $L \in \mathbb{R}^{n \times p}$ is an observer gain to be designed.

¹ The definition of a 1-framer can be found in Mazenc et al. (2012), roughly speaking it is an interval open-loop estimator independent of $y(t)$.

Assumption 3. There exist an invertible matrix $S \in \mathbb{R}^{n \times n}$ and $L \in \mathbb{R}^{n \times p}$ such that $S(A_1 - LC)S^{-1} = R_1$, where R_1 is a Metzler matrix and

$$R_1 = R_1^{\dagger} + R_1^{\ddagger}, \quad R_1^{\dagger} = \text{diag}[-r_{1,1}, \dots, -r_{1,n}], \quad R_1^{\ddagger} \geq 0$$

with R_1^{\dagger} is the diagonal matrix composed by all elements on the main diagonal of R_1 , $r_{1,i} > 0$ for all $i = 1, \dots, n$, and R_1^{\ddagger} is formed by the rest elements of R_1 out of the main diagonal.

The conditions of existence of such matrices S and L can be found in Raïssi et al. (2012), in particular Assumption 3 is satisfied if the pair (A_1, C) is observable, then they can be expressed as a LMI with respect to $S \in \mathbb{R}^{n \times n}$ and $W \in \mathbb{R}^{n \times p}$ for a fixed Metzler matrix R_1 :

$$SA_1 - WC = R_1 S \quad (10)$$

with $L = S^{-1}W$ (if the matrix R_1 is considered as a variable, then it is a bilinear matrix inequality; for its solution a grid of admissible values of R_1 can be used with posterior resolution of the LMI (10) for each candidate of R_1). Under this assumption in the new coordinates $z = Sx$ the system (7) takes the form:

$$\dot{z}(t) = R_0 z(t) + R_1 z[h(t)] + SLy(t) + \beta(t), \quad (11)$$

where $R_0 = SA_0 S^{-1}$ and $\beta(t) = S[b(t) - Lv(t)]$ is a new additive uncertain input, the initial condition $z_0 = Sx_0 \in \mathcal{C}_{\bar{\tau}}^n$ and

$$\underline{z}_0 \leq z_0 \leq \bar{z}_0,$$

where $\underline{z}_0 = S^+ x_0 - S^- \bar{x}_0$ and $\bar{z}_0 = S^+ \bar{x}_0 - S^- x_0$ are calculated using (6), $\underline{z}_0, \bar{z}_0 \in \mathcal{C}_{\bar{\tau}}^n$. From Assumption 2 and the relations (6) we obtain that

$$\underline{\beta}(t) \leq \beta(t) \leq \bar{\beta}(t) \quad \forall t \geq 0,$$

where $\underline{\beta}(t) = S^+ \underline{b}(t) - S^- \bar{b}(t) - (SL)^+ \bar{v}(t) + (SL)^- \underline{v}(t)$ and $\bar{\beta}(t) = S^+ \bar{b}(t) - S^- \underline{b}(t) - (SL)^+ \underline{v}(t) + (SL)^- \bar{v}(t)$. Then the following interval observer can be proposed for the representation (11):

$$\dot{\underline{z}}(t) = R_0^+ \underline{z}(t) - R_0^- \bar{z}(t) + R_1 \underline{z}[h(t)] + SLy(t) + \underline{\beta}(t) - \delta,$$

$$\dot{\bar{z}}(t) = R_0^+ \bar{z}(t) - R_0^- \underline{z}(t) + R_1 \bar{z}[h(t)] + SLy(t) + \bar{\beta}(t) + \delta,$$

$$\delta = [\delta_1, \dots, \delta_n]^T, \quad (12)$$

$$\delta_i = \begin{cases} r_{1,i} \|\bar{z}_{0,i} - \underline{z}_{0,i}\| & \text{if } t \leq \bar{\tau} \\ 0 & \text{otherwise,} \end{cases} \quad i = 1, \dots, n$$

with initial conditions $\underline{z}_0, \bar{z}_0$ for the variables $\underline{z}(t), \bar{z}(t)$ respectively. Finally interval estimates for the variable $x(t)$ can also be obtained using (6):

$$\underline{x}(t) = (S^{-1})^+ \underline{z}(t) - (S^{-1})^- \bar{z}(t), \quad (13)$$

$$\bar{x}(t) = (S^{-1})^+ \bar{z}(t) - (S^{-1})^- \underline{z}(t),$$

which may be conservative, see discussion and improved solutions in Rapaport and Gouzé (2003). For all $i = 1, \dots, n$ denote

$$r_{0,i} = (R_0^+)^T_{i,i}.$$

Proposition 10. Let Assumptions 1–3 be satisfied and

$$r_{0,i} \leq e r_{1,i} < r_{0,i} + \bar{\tau}^{-1}$$

for all $i = 1, \dots, n$. Then the relations

$$\underline{x}(t) \leq x(t) \leq \bar{x}(t) \quad \forall t \geq 0 \quad (14)$$

hold for the system (7) and the interval observer (12), (13). If in addition there exist symmetric matrices $P \in \mathbb{R}^{2n \times 2n}, \Sigma \in \mathbb{R}^{2n \times 2n}, \mathcal{E} \in \mathbb{R}^{2n \times 2n}$ and $\Theta \in \mathbb{R}^{2n \times 2n}$ such that the LMIs

$$\begin{bmatrix} \mathcal{E} & \Theta \\ \Theta & \mathcal{E} \end{bmatrix} \geq 0, \quad P > 0, \quad \Sigma > 0, \quad \mathcal{E} > 0, \quad (15)$$

$$\begin{bmatrix} \Phi_0^T P + P \Phi_0 + \Sigma - \mathcal{E} & \Theta & P \Phi_1 + \mathcal{E} - \Theta & \bar{\tau} \Phi_0^T \mathcal{E} \\ \Theta & -\Sigma - \mathcal{E} & \mathcal{E} - \Theta & 0_{2n \times 2n} \\ \Phi_1^T P + \mathcal{E} - \Theta & \mathcal{E} - \Theta & \Theta + \Theta^T - 2\mathcal{E} & \bar{\tau} \Phi_1^T \mathcal{E} \\ \bar{\tau} \mathcal{E} \Phi_0 & 0_{2n \times 2n} & \bar{\tau} \mathcal{E} \Phi_1 & -\mathcal{E} \end{bmatrix} < 0,$$

where

$$\Phi_0 = \begin{bmatrix} R_0^+ & R_0^- \\ R_0^- & R_0^+ \end{bmatrix}, \quad \Phi_1 = \begin{bmatrix} R_1 & 0_{n \times n} \\ 0_{n \times n} & R_1 \end{bmatrix},$$

are satisfied, then $x - \underline{x}, \bar{x} - x \in \mathcal{L}_\infty^n$.

Proof. Introduce the interval estimation errors $\underline{e} = z - \underline{z}$ and $\bar{e} = \bar{z} - z$ for the observer (12) and (11):

$$\dot{\underline{e}}(t) = R_0^+ \underline{e}(t) + R_0^- \bar{e}(t) + R_1 e[h(t)] + \beta(t) - \underline{\beta}(t) + \delta,$$

$$\dot{\bar{e}}(t) = R_0^+ \bar{e}(t) + R_0^- \underline{e}(t) + R_1 \bar{e}[h(t)] + \bar{\beta}(t) - \beta(t) + \delta,$$

which for any $i = 1, \dots, n$ may be rewritten as follows:

$$\begin{aligned} \dot{\underline{e}}_i(t) &= r_{0,i} \underline{e}_i(t) - r_{1,i} e_i[h(t)] + \underline{\chi}_i(t) \\ &\quad + \beta_i(t) - \underline{\beta}_i(t) + \delta_i, \end{aligned} \quad (16)$$

$$\begin{aligned} \dot{\bar{e}}_i(t) &= r_{0,i} \bar{e}_i(t) - r_{1,0} \bar{e}_i[h(t)] + \bar{\chi}_i(t) \\ &\quad + \bar{\beta}_i(t) - \beta_i(t) + \delta_i, \end{aligned} \quad (17)$$

where

$$\underline{\chi}_i(t) = \sum_{j=1, j \neq i}^n (R_0^+)_{i,j} \underline{e}_j(t) + \sum_{k=1}^n (R_0^-)_{i,k} \bar{e}_k(t) + \sum_{j=1}^n (R_1)_{i,j} \underline{e}_j(t),$$

$$\bar{\chi}_i(t) = \sum_{j=1, j \neq i}^n (R_0^+)_{i,j} \bar{e}_j(t) + \sum_{k=1}^n (R_0^-)_{i,k} \underline{e}_k(t) + \sum_{j=1}^n (R_1)_{i,j} \bar{e}_j(t).$$

The relations $\beta_i(t) - \underline{\beta}_i(t) \geq 0, \bar{\beta}_i(t) - \beta_i(t) \geq 0$ for all $t \geq 0$ and $\delta \geq 0$ are satisfied by construction, for all $i = 1, \dots, n$. The signals $\underline{\chi}_i(t) \geq 0$ and $\bar{\chi}_i(t) \geq 0$ for all $t \geq 0$ and $i = 1, \dots, n$ provided that $\underline{e}(t) \geq 0$ and $\bar{e}(t) \geq 0$. Note that for the systems (16), (17) all conditions of Proposition 6 are satisfied due to the selection of δ , thus by induction if $\underline{e}(0) \geq 0$ and $\bar{e}(0) \geq 0$, this property is preserved for all $t \geq 0$:

$$\underline{e}(t) \geq 0, \quad \bar{e}(t) \geq 0.$$

Therefore, from (13) the required property (14) is valid.

In order to prove boundedness of $x - \underline{x}, \bar{x} - x$ consider a Lyapunov functional candidate from Fridman (2014) and Park, Ko, and Jeong (2011):

$$\begin{aligned} V(t, \zeta_t, \dot{\zeta}_t) &= \zeta^T(t) P \zeta(t) + \int_{t-\bar{\tau}}^t \zeta^T(s) \Sigma \zeta(s) ds \\ &\quad + \bar{\tau} \int_{-\bar{\tau}}^0 \int_{t+\theta}^t \dot{\zeta}^T(s) \Xi \dot{\zeta}(s) ds d\theta, \end{aligned} \quad (18)$$

where $\zeta = [\underline{e}^T \quad \bar{e}^T]^T$ is the combined error vector of the observer (12), and dynamics of ζ have the form:

$$\dot{\zeta}(t) = \Phi_0 \zeta(t) + \Phi_1 \zeta[h(t)] + \begin{bmatrix} \beta(t) - \underline{\beta}(t) \\ \bar{\beta}(t) - \beta(t) \end{bmatrix} + \begin{bmatrix} I_n \\ I_n \end{bmatrix} \delta,$$

where the matrices Φ_0 and Φ_1 are defined in the proposition formulation. The LMIs (15) imply stability of this system (Fridman, 2014; Park et al., 2011), and boundedness of $\zeta(t)$ for any bounded input.

The LMIs (15) ensure stability of (16), (17), they can be modified (Fridman, 2014) in order to ensure a desired gain from the inputs $\beta - \underline{\beta}, \bar{\beta} - \beta$ to the estimation errors \underline{e}, \bar{e} optimizing the interval estimation accuracy. Such a modification is omitted for brevity of presentation.

Remark 11. The restrictions imposed in Proposition 10 on all matrices S, L, P, Σ, Ξ and Θ , which are needed to design interval observer (12), are interrelated and nonlinear, therefore, it is hard

to represent them in a LMI form directly. It is proposed to decouple these conditions: on the LMI (10) from Assumption 3 (if L and S are fixed, then the matrices R_0 and R_1 become given, and vice versa) and the LMI (15) with respect to P, Σ, Ξ and Θ . Such a two step scheme can be iterated for different selections of R_1 , until a solution is found.

An alternative procedure can be provided assuming that $S = I_n$ and $\Xi = \mu P$ for some scalar tuning parameter $\mu > 0$, then the above conditions can be rewritten as a series of bilinear matrix inequalities:

$$\begin{aligned} P\Phi_1 - W \begin{bmatrix} C \\ C \end{bmatrix} + \Upsilon &\geq 0, \quad P > 0, \quad \Sigma > 0, \quad \Upsilon \geq 0, \\ \begin{bmatrix} \mu P & \Theta \\ \Theta & \mu P \end{bmatrix} &\geq 0, \quad \Phi_0 = \begin{bmatrix} A_0^+ & A_0^- \\ A_0^- & A_0^+ \end{bmatrix}, \quad \Phi_1 = \begin{bmatrix} A_1 & 0_{n \times n} \\ 0_{n \times n} & A_1 \end{bmatrix}, \\ \begin{bmatrix} \Phi_0^T P + P \Phi_0 + \Sigma - \mu P & \Theta & \Phi_2 & \bar{\tau} \mu \Phi_0^T P \\ \Theta & -\Sigma - \mu P & \mu P - \Theta & 0_{2n \times 2n} \\ \Phi_2^T & \mu P - \Theta & \Theta + \Theta^T - 2\mu P & \Phi_3^T \\ \bar{\tau} \mu P \Phi_0 & 0_{2n \times 2n} & \Phi_3 & -\mu P \end{bmatrix} &< 0, \\ \Phi_2 &= P\Phi_1 - W \begin{bmatrix} C \\ C \end{bmatrix} + \mu P - \Theta, \quad \Phi_3 = \bar{\tau} \mu \left(P\Phi_1 - W \begin{bmatrix} C \\ C \end{bmatrix} \right), \end{aligned}$$

for symmetric matrices $P \in \mathbb{R}^{2n \times 2n}, \Sigma \in \mathbb{R}^{2n \times 2n}, \Upsilon \in \mathbb{R}^{2n \times 2n}$ and $\Theta \in \mathbb{R}^{2n \times 2n}, \Upsilon$ and P should also be declared diagonal, $W \in \mathbb{R}^{2n \times 2p}$ is a matrix block-diagonal variable, then $L = P^{-1}W$. For any fixed value of μ the above system becomes a LMI and it can be efficiently solved with respect to L, P, Σ and Θ (and W, Υ).

The result of Proposition 10 is based on a rather restrictive Assumption 3, that the matrix $A_1 - LC$ is Hurwitz. In many cases (if, for example, the output y measurements are available with delays, but the system itself has no delayed dynamics) this assumption cannot be verified and may be relaxed as follows.

Assumption 4. There exist an invertible matrix $S \in \mathbb{R}^{n \times n}$ and $L \in \mathbb{R}^{n \times p}$ such that

$$\begin{aligned} S(A_1 - LC)S^{-1} &= Q_1 = \begin{bmatrix} \bar{Q}_1 & 0_{l \times n-l} \\ 0_{n-l \times l} & 0_{n-l \times n-l} \end{bmatrix}, \\ SA_0 S^{-1} &= Q_0 = \begin{bmatrix} Q_{0,1} & Q_{0,2} \\ Q_{0,3} & Q_{0,4} \end{bmatrix}, \\ Q_{0,1} \in \mathbb{R}^{l \times l}, \quad Q_{0,2} \in \mathbb{R}^{l \times n-l}, \quad Q_{0,3} \in \mathbb{R}^{n-l \times l}, \\ Q_{0,4} \in \mathbb{R}^{n-l \times n-l}, \quad \bar{Q}_1 &= \bar{Q}_1^\dagger + \bar{Q}_1^\ddagger, \quad Q_{0,4} = Q_{0,4}^\dagger + Q_{0,4}^\ddagger, \end{aligned}$$

where $\bar{Q}_1^\dagger = \text{diag}[-q_{1,1}, \dots, -q_{1,l}]$ with $q_{1,k} > 0$ for all $k = 1, \dots, l, \bar{Q}_1^\ddagger \geq 0$, and $0 < l \leq n$.

As before $\bar{Q}_1^\dagger, Q_{0,4}^\dagger$ are diagonal matrices composed by all elements on the main diagonals of \bar{Q}_1 and $Q_{0,4}$ respectively, and $\bar{Q}_1^\ddagger, Q_{0,4}^\ddagger$ are formed by the rest elements of \bar{Q}_1 and $Q_{0,4}$ out of the main diagonals. In this case it is assumed that some part of the system (7) cannot be stabilized by a linear output injection. In the new coordinates $z = Sx = [z_1^T \ z_2^T]^T, z_1 \in \mathbb{R}^l, z_2 \in \mathbb{R}^{n-l}$ the system (7) takes the form:

$$\begin{aligned} \dot{z}_1(t) &= \bar{Q}_0 z(t) + \bar{Q}_1 z_1[h(t)] + \Lambda_1 y(t) + \beta_1(t), \\ \dot{z}_2(t) &= Q_{0,3} z_1(t) + Q_{0,4} z_2(t) + \Lambda_2 y(t) + \beta_2(t), \end{aligned} \quad (19)$$

where $\bar{Q}_0 = [Q_{0,1} \ Q_{0,2}]$ and $SL = [A_1^T \ A_2^T]^T$ are the matrices of appropriate dimensions; and the input $\beta(t) = [\beta_1^T(t) \ \beta_2^T(t)]^T = S[b(t) - Lv(t)]$ with the initial condition $z_0 = [z_{01}^T \ z_{02}^T]^T = Sx_0 \in \mathcal{C}_{\bar{\tau}}^n$ have the same form and interval bounds as for (11). Then the

following interval observer can be proposed for the representation (19) instead of (12):

$$\begin{aligned}\dot{\underline{z}}_1(t) &= \overline{Q}_0^+ \underline{z}(t) - \overline{Q}_0^- \overline{z}(t) + \overline{Q}_1 z_1[h(t)] + \Lambda_1 y(t) + \underline{\beta}_1(t) - \delta^l, \\ \dot{\overline{z}}_1(t) &= \overline{Q}_0^+ \overline{z}(t) - \overline{Q}_0^- \underline{z}(t) + \overline{Q}_1 \overline{z}_1[h(t)] + \Lambda_1 y(t) + \overline{\beta}_1(t) + \delta^l, \\ \dot{\underline{z}}_2(t) &= Q_{0,3}^+ \underline{z}_1(t) - Q_{0,3}^- \overline{z}_1(t) + Q_{0,4}^+ \underline{z}_2(t) + (Q_{0,4}^i)^+ \underline{z}_2(t) \\ &\quad - (Q_{0,4}^i)^- \overline{z}_2(t) + \Lambda_2 y(t) + \underline{\beta}_2(t), \\ \dot{\overline{z}}_2(t) &= Q_{0,3}^+ \overline{z}_1(t) - Q_{0,3}^- \underline{z}_1(t) + Q_{0,4}^+ \overline{z}_2(t) + (Q_{0,4}^i)^+ \overline{z}_2(t) \\ &\quad - (Q_{0,4}^i)^- \underline{z}_2(t) + \Lambda_2 y(t) + \overline{\beta}_2(t), \\ \delta^l &= [\delta_1^l, \dots, \delta_l^l]^T, \\ \delta_k^l &= \begin{cases} q_{1,k} \|\overline{z}_{0,k} - z_{0,k}\| & \text{if } t \leq \overline{\tau} \\ 0 & \text{otherwise,} \end{cases} \quad k = 1, \dots, l\end{aligned}\quad (20)$$

with initial conditions $z_0, \overline{z}_0 \in \mathbb{C}_n^{\mathbb{R}}$ for the variables $z(t) = [z_1^T(t) \ z_2^T(t)]^T$, $\overline{z}(t) = [\overline{z}_1^T(t) \ \overline{z}_2^T(t)]^T$ respectively. Finally interval estimates for the variable $x(t)$ can also be obtained using (13). For all $k = 1, \dots, l$ denote

$$q_{0,k} = (\overline{Q}_0^+)^{k,k}.$$

Theorem 12. Let Assumptions 1, 2 and 4 be satisfied and

$$q_{0,k} \leq e q_{1,k} < q_{0,k} + \overline{\tau}^{-1}$$

for all $k = 1, \dots, l$. Then the interval observer (13), (20) for the system (7) admits the relations (14). If in addition there exist symmetric matrices $P \in \mathbb{R}^{2n \times 2n}$, $\Sigma \in \mathbb{R}^{2n \times 2n}$, $\Xi \in \mathbb{R}^{2n \times 2n}$ and $\Theta \in \mathbb{R}^{2n \times 2n}$ such that the LMIs (15) are satisfied for

$$\begin{aligned}\Phi_0 &= \begin{bmatrix} Q_{01}^+ & Q_{01}^- & Q_{02}^+ & Q_{02}^- \\ Q_{01}^- & Q_{01}^+ & Q_{02}^- & Q_{02}^+ \\ Q_{0,3}^+ & Q_{0,3}^- & Q_{0,4}^+ + (Q_{0,4}^i)^+ & (Q_{0,4}^i)^- \\ Q_{0,3}^- & Q_{0,3}^+ & (Q_{0,4}^i)^- & Q_{0,4}^+ + (Q_{0,4}^i)^+ \end{bmatrix}, \\ \Phi_1 &= \begin{bmatrix} \overline{Q}_1 & 0_{l \times l} & 0_{l \times n-l} & 0_{l \times n-l} \\ 0_{l \times l} & \overline{Q}_1 & 0_{l \times n-l} & 0_{l \times n-l} \\ 0_{n-l \times l} & 0_{n-l \times l} & 0_{n-l \times n-l} & 0_{n-l \times n-l} \\ 0_{n-l \times l} & 0_{n-l \times l} & 0_{n-l \times n-l} & 0_{n-l \times n-l} \end{bmatrix},\end{aligned}$$

then $x - \underline{x}, \overline{x} - x \in \mathcal{L}_\infty^n$.

Proof. Introduce the interval estimation errors $\underline{e} = z - \underline{z} = [\underline{e}_1^T \ \underline{e}_2^T]^T$ and $\overline{e} = \overline{z} - z = [\overline{e}_1^T \ \overline{e}_2^T]^T$ for the observer (20) and (19):

$$\begin{aligned}\dot{\underline{e}}_1(t) &= \overline{Q}_0^+ \underline{e}(t) + \overline{Q}_0^- \overline{e}(t) + \overline{Q}_1 \underline{e}_1[h(t)] + \beta_1(t) - \underline{\beta}_1(t) + \delta^l, \\ \dot{\overline{e}}_1(t) &= \overline{Q}_0^+ \overline{e}(t) + \overline{Q}_0^- \underline{e}(t) + \overline{Q}_1 \overline{e}_1[h(t)] + \overline{\beta}_1(t) - \beta_1(t) + \delta^l, \\ \dot{\underline{e}}_2(t) &= Q_{0,3}^+ \underline{e}_1(t) + Q_{0,3}^- \overline{e}_1(t) + [Q_{0,4}^+ + (Q_{0,4}^i)^+] \underline{e}_2(t) \\ &\quad + (Q_{0,4}^i)^- \overline{e}_2(t) + \beta_2(t) - \underline{\beta}_2(t), \\ \dot{\overline{e}}_2(t) &= Q_{0,3}^+ \overline{e}_1(t) + Q_{0,3}^- \underline{e}_1(t) + [Q_{0,4}^+ + (Q_{0,4}^i)^+] \overline{e}_2(t) \\ &\quad + (Q_{0,4}^i)^- \underline{e}_2(t) + \overline{\beta}_2(t) - \beta_2(t).\end{aligned}$$

It is easy to see that positivity analysis for the variables $\underline{e}_1(t)$ and $\overline{e}_1(t)$ is similar to the one given in the proof of Proposition 10, while for the variables $\underline{e}_2(t)$ and $\overline{e}_2(t)$ the positivity follows the fact that the matrix $Q_{0,4}^+ + (Q_{0,4}^i)^+$ is Metzler by construction and the rest terms on the right-hand side of $\dot{\underline{e}}_2, \dot{\overline{e}}_2$ are nonnegative provided that $\underline{e}(t) \geq 0$ and $\overline{e}(t) \geq 0$. By induction, if $\underline{e}(0) \geq 0$ and $\overline{e}(0) \geq 0$, then the relations $\underline{e}(t) \geq 0, \overline{e}(t) \geq 0$ are preserved for all $t \geq 0$ (Smith, 1995). Therefore, from (13) the inclusion (14) is valid.

In order to prove boundedness of $\underline{x}, \overline{x}$ consider a Lyapunov functional candidate (18) from Fridman (2014) and Park et al. (2011), where $\zeta = [\underline{e}_1^T \ \overline{e}_1^T \ \underline{e}_2^T \ \overline{e}_2^T]^T$ with

$$\dot{\zeta}(t) = \Phi_0 \zeta(t) + \Phi_1 \zeta[h(t)] + \begin{bmatrix} \beta_1(t) - \underline{\beta}_1(t) \\ \overline{\beta}_1(t) - \beta_1(t) \\ \beta_2(t) - \underline{\beta}_2(t) \\ \overline{\beta}_2(t) - \beta_2(t) \end{bmatrix} + \begin{bmatrix} I_l \\ I_l \\ 0_{n-l \times l} \\ 0_{n-l \times l} \end{bmatrix} \delta^l,$$

and the matrices Φ_0 and Φ_1 are defined in the theorem formulation. The LMIs (15) imply stability of this system (Fridman, 2014; Park et al., 2011), and boundedness of solutions for any bounded inputs.

Remark 13. It has been assumed before that the delay $h(t)$ is time-varying and known, the latter restriction can be relaxed rewriting the Eqs. (19) as follows:

$$\begin{aligned}\dot{z}_1(t) &= \overline{Q}_0 z(t) + \overline{Q}_1 z_1[t - \overline{\tau}] + \overline{Q}_1 \{z_1[h(t)] - z_1[t - \overline{\tau}]\} \\ &\quad + \Lambda_1 y(t) + \beta_1(t), \\ \dot{z}_2(t) &= Q_{0,3} z_1(t) + Q_{0,4} z_2(t) + \Lambda_2 y(t) + \beta_2(t),\end{aligned}$$

where as in Efimov et al. (2013) it is possible to calculate an interval inclusion:

$$\begin{aligned}q_1(t) &\leq \overline{Q}_1 \{z_1[h(t)] - z_1[t - \overline{\tau}]\} \leq \overline{q}_1(t), \\ q_1(t) &= \min_{s \in [t - \overline{\tau}, t]} \left\{ \overline{Q}_1^+ (\overline{z}_1[s] - z_1[t - \overline{\tau}]) + \overline{Q}_1^- (z_1[s] - \overline{z}_1[t - \overline{\tau}]) \right\}, \\ \overline{q}_1(t) &= \max_{s \in [t - \overline{\tau}, t]} \left\{ \overline{Q}_1^+ (z_1[s] - \overline{z}_1[t - \overline{\tau}]) + \overline{Q}_1^- (\overline{z}_1[s] - z_1[t - \overline{\tau}]) \right\}\end{aligned}$$

provided that $\underline{z}_1(\theta) \leq z_1(\theta) \leq \overline{z}_1(\theta)$ for all $\theta \geq -\overline{\tau}$, where $\underline{q}_1(t)$ and $\overline{q}_1(t)$ can be derived on-line. Then the term containing uncertain time-varying delay $\overline{Q}_1 \{z_1[h(t)] - z_1[t - \overline{\tau}]\}$ can be treated as a part of $\beta_1(t)$, and interval observer (13), (20) can be applied taking into account only the maximal admissible delay $\overline{\tau}$ (see the pendulum example in Section 5). Another approach that can be used to treat uncertain time-varying delays (skipping $\underline{q}_1(t)$ and $\overline{q}_1(t)$) is presented in Ait Rami et al. (2013).

Remark 14. Though all results in the paper are formulated for a linear system (7), they can also be applied to nonlinear ones, provided that nonlinearities are functions of measured outputs and inputs. Such a case is illustrated by the pendulum example below.

5. Examples

5.1. Motivating example

To illustrate the result of Claim 9 for the system (8) let us consider (7) for $n = 1$

$$\dot{x}(t) = u(t) + d(t), \quad y(t) = x(t - \tau(t)) + v(t),$$

where $x(t) \in \mathbb{R}$ is the state, $u(t) = \sin(t)$ is the system known input, $d(t) \in [-0.1, 0.1]$ is the input disturbance, $v(t) \in [-0.1, 0.1]$ is the measurement noise, and $\tau(t) = \frac{1}{2.02e}(1 + \sin(0.5t))$ with $\overline{\tau} = \frac{1}{1.01e}$. We can rewrite this system as follows:

$$\dot{x}(t) = -x(t - \tau(t)) + b(t),$$

$$b(t) = y(t) + u(t) + d(t) - v(t)$$

with $\underline{b}(t) = y(t) + u(t) - 0.2$ and $\overline{b}(t) = y(t) + u(t) + 0.2$, where now $x(\theta) = x(0)$ for all $\theta \in [-\overline{\tau}, 0)$. Assume that $\|x_0\| \leq 5$. For $L = 0$ and $S = 1$ the interval observer (12) takes a form similar to the 1-framer from Claim 9, and all conditions of this claim or Proposition 10 are satisfied. The results of simulation for

$$d(t) = 0.1 \cos(3t), \quad v(t) = 0.1 \sin(5t)$$

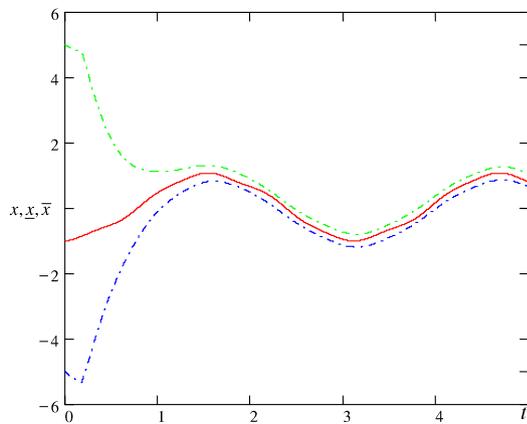

Fig. 2. The results of simulation for the motivating example. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

are shown in Fig. 2. The red solid curve represents a trajectory of the system $x(t)$, the blue and green dash-dot lines correspond to the interval estimates $\underline{x}(t)$ and $\bar{x}(t)$ generated by the interval observer. As we can conclude from Fig. 2, the inclusion $\underline{x}(t) \leq x(t) \leq \bar{x}(t)$ is ensured for all $t \geq 0$, and asymptotically the width of the interval $[\underline{x}(t), \bar{x}(t)]$ is proportional to the system uncertainty.

5.2. A pendulum example

Consider an example of (7) for $n = 2$

$$\begin{aligned} \dot{x}_1(t) &= x_2(t), & y(t) &= x_1(t - \tau(t)), \\ \dot{x}_2(t) &= 0.1x_1(t) - 0.5x_2(t) - 0.35 \sin[x_1(t - \hat{\tau}(t))] + \sin(1.25t), \end{aligned}$$

where $0 \leq \tau(t) \leq \bar{\tau}$ is a delay of measurements and $1 \leq \hat{\tau}(t) \leq 2$ is an uncertain time varying delay in the state equation (for simulation we selected $\tau(t) = 0.24 + 0.12 \sin(t)$ and $\hat{\tau}(t) = 1 + \sin^2(2t)$). The models of nonlinear delayed pendulums appear in microgrid control systems (Efimov, Ortega, & Schiffer, 2015). Thus, in this case

$$A_0 = \begin{bmatrix} 0 & 1 \\ 0.1 & -0.5 \end{bmatrix}, \quad A_1 = 0,$$

$$h(t) = t - \tau(t), \quad \underline{\tau} = 0.36, \quad v(t) = 0,$$

$$b(t) = \begin{bmatrix} 0 \\ -0.35 \sin[y(t - \hat{\tau}(t) + \tau(t))] + \sin(1.25t) \end{bmatrix},$$

and Assumption 2 is satisfied for:

$$\begin{aligned} \underline{b}(t) &= \begin{bmatrix} 0 \\ \min_{\theta \in [1,2]} \{-0.35 \sin[y(t - \theta + \tau(t))]\} + \sin(1.25t) \end{bmatrix}, \\ \bar{b}(t) &= \begin{bmatrix} 0 \\ \max_{\theta \in [1,2]} \{-0.35 \sin[y(t - \theta + \tau(t))]\} + \sin(1.25t) \end{bmatrix}. \end{aligned}$$

The results of simulation in Fig. 3 show that for the initial conditions $\|x_{10}\| \leq 1$, $\|x_{20}\| \leq 1$ Assumption 1 is also satisfied. For $L = [1 \ 0]^T$ and $S = I_2$ the conditions of Assumption 4 are verified, then $z = x$. The LMIs of Theorem 12 are satisfied for the given value of $\bar{\tau} = 0.36$. The results of simulation are shown in Fig. 3, they confirm efficiency of interval estimation and validity of delay-dependent positivity conditions (the stability conditions of Theorem 12 are satisfied for $\bar{\tau} \leq 1.3$ in this example, but for $0.37 \leq \bar{\tau} \leq 1.3$ the positivity conditions of Proposition 6 are not satisfied and the interval estimation cannot be guaranteed).

6. Conclusion

In the paper, new interval observers for linear time-delay systems with delayed measurements have been designed extending

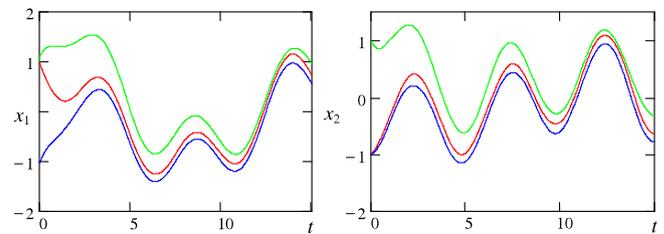

Fig. 3. The results of simulation for the delayed pendulum.

the theory of Efimov et al. (2013, 2015) and Mazenc et al. (2012). For this goal, new delay-dependent positivity conditions for linear systems with time-varying delays have been proposed. These conditions are related with non-oscillatory behavior of solutions (Agarwal et al., 2012). They nicely complement the existing delay-independent conditions of Haddad and Chellaboina (2004) (see Fig. 1). The results have been applied for the benchmark system from Mazenc et al. (2012). Two interval observers have been proposed for the cases of observable or detectable systems. The efficacy of observers has been illustrated by numerical experiments. Extension of these results for the case of sampled-data measurements is a direction of future research.

Denis Efimov received the Ph.D. degree in Automatic Control from the Saint-Petersburg State Electrical Engineering University (Russia) in 2001, and the Dr.Sc. degree in Automatic control in 2006 from Institute for Problems of Mechanical Engineering RAS (Saint-Petersburg, Russia). From 2000 to 2009 he was research fellow of the Institute for Problems of Mechanical Engineering RAS, Control of Complex Systems Laboratory. From 2006 to 2011 he was working in the LSS (Supelec, France), the Montefiore Institute (University of Liege, Belgium) and the Automatic control group at IMS lab (University of Bordeaux I, France). Since 2011 he joined the Non-A team at Inria Lille center. He is a member of several IFAC TCs and a Senior member of IEEE. His main research interests include nonlinear oscillation analysis, observation and control, switched and nonlinear system stability.

Emilia Fridman received the M.Sc. degree from Kuibyshev State University, USSR, in 1981 and the Ph.D. degree from Voronezh State University, USSR, in 1986, all in mathematics. From 1986 to 1992 she was an Assistant and Associate Professor in the Department of Mathematics at Kuibyshev Institute of Railway Engineers, USSR. Since 1993 she has been at Tel Aviv University, where she is currently Professor of Electrical Engineering-Systems. She has held visiting positions at the Weierstrass Institute for Applied Analysis and Stochastics in Berlin (Germany), INRIA in Rocquencourt (France), Ecole Centrale de Lille (France), Valenciennes University (France), Leicester University (UK), Kent University (UK), CINVESTAV (Mexico), Zhejiang University (China), St. Petersburg IPM (Russia), Melbourne University (Australia), Supelec (France), KTH (Sweden).

Her research interests include time-delay systems, networked control systems, distributed parameter systems, robust control, singular perturbations and

nonlinear control. She has published more than 100 articles in international scientific journals. She is the author of the monograph “Introduction to Time-Delay Systems: Analysis and Control” (Birkhauser, 2014). In 2014 she was Nominated as a Highly Cited Researcher by Thomson ISI. Currently she serves as Associate Editor in *Automatica* and *SIAM Journal on Control and Optimization*.

Andrey Polyakov received Ph.D. degree in Systems Analysis and Control from Voronezh State University in 2005. Till 2010 he was an assistant professor with this university. In 2007–2008, Dr. Polyakov was working at CINVESTAV center in Mexico. From 2010 up to 2013 he was Leader Researcher of the Institute of the Control Sciences, Russian Academy of Sciences. Since 2013 he joined the Non-A team of Inria in Lille, France. He is the editor of *International Journal of Robust and Nonlinear Control*, *Journal of Optimization Theory and Applications* (JOTA), *Automation and Remote Control* and a member of IFAC TC 2.3 Non-Linear Control Systems. He is co-author of the book “Attractive Ellipsoids in Robust Control”, Birkhauser. His main research interests include non-asymptotic methods of robust control and estimation, Lyapunov methods for time-delay, nonlinear and discontinuous control systems.

Wilfrid Perruquetti was born in 1968 in Saint Gilles, France. In 1991, he received a M.Sc. in Automatic Control and graduated from “Institut Industriel du Nord” (French “Grande Ecole”). In 1994, he obtained a Ph.D. in Automatic Control, then joined the “Ecole Centrale de Lille” (French “Grande Ecole”) as an Assistant Professor in 1995, where he is actually Full Professor (since 2003). He belongs to CRISTAL (CNRS) and to the Non-A project (INRIA Lille-Nord-Europe). He is vice-deputy of INS2I CNRS, permanent head of Non-A INRIA, and was from (2010–2014) scientific project manager at ANR, from (2007–2009) a representative of the French Ministry of Education and Research (DGRI). He is member of several councils and of several societies (IFAC, TC 1.3, 2.3, 2.5 (past) and 9.2 (Chair), SEE member). He has published more than 170 journal, book chapters and conference papers (more than 60 journal papers) and is co-editor with Jean-Pierre Barbot of the books “Sliding Mode Control in Engineering”, Marcel Dekker and “Chaos in Automatic control”, CRC Taylor & Francis.

He is currently working on stability analysis (including various kinds of stability concepts), stabilization (in particular finite-time stabilization), sliding mode control of nonlinear and delay systems, observation of state variables and identification of system parameters. His main fields of application concern robotics, in particular mobile robots (path planning, stabilization, coordination, etc.), robotic manipulators (trajectory generation and control) and electrical actuators (DC motor, induction motor, stepper motor, etc.).

Jean-Pierre Richard was born in Montpellier (France) in 1956. He received his Dipl. Eng. in 1979, M.Sc. in Electronics 1979, Ph.D. in Automatic Control 1981, D.Sc. in Physical Sciences 1984 (University of Lille), IEEE SM 1998. He is presently a Professor at Centrale Lille (French “Grande Ecole”) with the research laboratory CRISTAL CNRS UMR 9189 together with the research center Inria Lille North-Europe. He is heading the Inria project-team Non-A (Non-Asymptotic estimation for online systems), manager of the CRISTAL group CO2 (for “Control and scientific Computing”) and director of the professional training “Research” of Centrale Lille. His current research mainly concerns time delay systems (stability, control, observation, identification, estimation) and their applications in networked control systems (teleoperation via unreliable networks, asynchronous sampling, complexity) and aerodynamics (active flow control). More details on his books, publications, advised Ph.D.s, collective responsibilities and awards, as well as some lectures and videos, can be found at <http://researchers.lille.inria.fr/~jrichard>.
